

# Acquisition

CSC 388

# Module Objectives

- ▶ List digital evidence storage formats
- ▶ Explain ways to determine the best acquisition method
- ▶ Describe contingency planning for data acquisitions
- ▶ Explain how to acquire and validate evidence
- ▶ Describe RAID acquisition methods
- ▶ Explain how to use remote network acquisition tools

# Digital Evidence Formats

# Format Options

- ▶ Data in a forensics acquisition tool is stored as an image file
- ▶ Three most common formats
  - ▶ Raw format
  - ▶ Proprietary formats
  - ▶ Advanced Forensics Format (AFF)

# Raw Format

- ▶ Makes it possible to write bit-stream data to files
- ▶ Advantages
  - ▶ Fast data transfers
  - ▶ Ignores minor data read errors on source drive
  - ▶ Most computer forensics tools can read raw format
- ▶ Disadvantages
  - ▶ Requires as much storage as original disk or data
  - ▶ Tools might not collect marginal (bad) sectors

# Proprietary Options

- ▶ Most forensics tools have their own formats
- ▶ Features offered
  - ▶ Option to compress or not compress image files
  - ▶ Can split an image into smaller segmented files
  - ▶ Can integrate metadata into the image file
- ▶ Disadvantages
  - ▶ Inability to share an image between different tools
  - ▶ File size limitation for each segmented volume
- ▶ The Expert Witness Compression format is unofficial standard

# Advanced Forensics Format (AFF)

- ▶ Developed by Dr. Simson L. Garfinkel as an open-source acquisition format
- ▶ Design goals
  - ▶ Provide compressed or uncompressed image files
  - ▶ No size restriction for disk-to-image files
  - ▶ Provide space in the image file or segmented files for metadata
  - ▶ Simple design with extensibility
  - ▶ Open source for multiple platforms and Oss
  - ▶ Internal consistency checks for self-authentication
- ▶ File extensions include .afd for segmented image files and .afm for AFF metadata
- ▶ AFF is open source

# Acquisition Methods

# Static vs Live Acquisition

- ▶ Static Acquisition

- ▶ Also called a dead-box acquisition
- ▶ Image or clone is collected with machine powered off

- ▶ Live Acquisition

- ▶ Machine is powered on and there exists a situation where interacting with the machine is valuable
  - ▶ Memory acquisition
  - ▶ Full disk encryption

# Full Disk Methods

- ▶ Creating a disk-to-image file
  - ▶ Most common method and offers most flexibility
  - ▶ Can make more than one copy
  - ▶ Copies are bit-for-bit replications of the original drive
  - ▶ Compatible with many commercial forensics tools
- ▶ Creating a disk-to-disk
  - ▶ When disk-to-image copy is not possible
  - ▶ Tools can adjust disk's geometry configuration
  - ▶ Tools: EnCase and X-Ways

# Logical & Sparse Methods

- ▶ Logical Acquisition
  - ▶ Only captures specific files of interest to the case
  - ▶ Ex: Windows registry, web history, only images or documents
  - ▶ Won't see deleted items this route
- ▶ Sparse Acquisition
  - ▶ Like logical, but will additionally acquire unallocated (deleted) space on disk

# Considerations to Determine Method & Equipment

- ▶ Size of Disk
  - ▶ Lossless compression is useful (built into EWF, others)
- ▶ Time to perform acquisition
  - ▶ Would a logical acquisition do the job?
- ▶ Where the evidence is located

# Remember

- ▶ Murphy's Law
  - ▶ Always have a duplicate of your image file; particularly when you're releasing/returning evidence
  - ▶ Copy with two different tools (if practical)
- ▶ Certain areas of the disk may not be copied by all tools
  - ▶ Host Protected Area (HPA) - mostly allows for reporting different disk size information
- ▶ If the disk is encrypted AND the machine is powered off, suspect cooperation or other sources may be required

# Acquisition Tools

© 2019 Cengage. May not be copied, scanned, or duplicated, in whole or in part, except for use as permitted in a license distributed with a certain product or service or otherwise on a password-protected website for classroom use.

## Acquisition Devices (Disk-to-Disk or Disk- to-Image)

# Acquisition Using Windows

## Advantages

- Collection is convenient

- Images can immediately be processed

## Disadvantages

- Tools (generally) can't see the HPA if that's suspected to hold data

- Certain countries don't accept write blocking bridges for acquisition

# Acquisition Using a Live CD/DVD/USB

- ▶ Linux Examples (make sure a read-only mode exists / test first; always)
  - ▶ Kali
  - ▶ Knoppix
  - ▶ PALADIN
  - ▶ Other spins
- ▶ Win-FE
  - ▶ <https://brettshavers.com/brett-s-blog/entry/mini-winfe-10-and-winfe-10-updated>

# Basic Linux Commands for Disk Interaction

- ▶ **fdisk** lists, creates, deletes, and verifies partition
- ▶ **mkfs.<fstype>** formats a file system
- ▶ **dd** can be used for bit-for-bit copying of data (be careful...)
  - ▶ **dcfldd** is a more forensic centric data dump tool
- ▶ Other tools will vary widely by distribution
  - ▶ **ewfmount/ewfcapture/etc** powered by **libewf/libyal** are very useful in this situation
  - ▶ **Guymager** is a tool on Kali that can capture a well-formed EWF image for use with various forensic tools

# Capturing Images in Windows (Live & Static)

- ▶ Live w/ FTK Imager
- ▶ Static w/ FTK Imager
- ▶ \*We are operating **without** a write blocker in the lab environment, but when you are able and/or required **always** use a write blocking interface for static acquisitions

# Capturing Images in Linux (Static via Live CD/DVD/USB)

- ▶ Static w/ dd
- ▶ Static w/ ewfcapture
- ▶ \*Again, we are operating **without** a write blocker in the lab environment, but when you are able and/or required **always** use a write blocking interface for static acquisitions

# Validation Matters

- ▶ Validating evidence may be the most critical aspect of computer forensics
- ▶ Requires using calculating a [hash](#)
  - ▶ Identical data always results in the same hash
  - ▶ Infeasible to
    - ▶ Generate the data that results in a particular hash
    - ▶ Find two different messages with same hash value (re: [SHAttered](#))
  - ▶ Any change to source data should change hash significantly
- ▶ Validation techniques
  - ▶ CRC-32, MD5, and SHA-1 to SHA-512

# By Collection Tool

- ▶ dd
  - ▶ Generic hashing utilities against the file work as the file is an exact copy of the disk
  - ▶ Linux: md5sum shasum and sha2sum families of utilities
  - ▶ Windows: certutil can calculate certain hashes as can the Get-FileHash cmdlet
- ▶ dcfldd
  - ▶ Hashing can be included at runtime
  - ▶ **hash** option will select algorithm
  - ▶ **hashlog** option will store hash outputs
  - ▶ **vf** option will compare resulting image hash to original media
- ▶ Proprietary formats often include validation metadata

```
PS C:\Users\Shawn\Desktop\vmshare> Get-FileHash .\personnel.sql |format-list

Algorithm : SHA256
Hash      : 6AA80F66249B3BF22C68639EAB4D07DFC0EDC9BBA8165F8EDEFE702A8DED38C0
Path      : C:\Users\Shawn\Desktop\vmshare\personnel.sql

PS C:\Users\Shawn\Desktop\vmshare>
```

# RAID Acquisition

# RAID Can Be a Problem

- ▶ Acquisition of RAID drives can be challenging and frustrating because of how RAID systems are
  - ▶ Designed
  - ▶ Configured
  - ▶ Sized
- ▶ Size is the biggest concern
  - ▶ Many large storage systems now have exabytes of data

# Key Questions

- ▶ How much data storage is needed?
- ▶ What type of RAID is used?
- ▶ Do you need to have all drives connected?
- ▶ Do you have the right acquisition tool?
- ▶ Can the tool read a forensically copied RAID image?
- ▶ Can the tool read split data saves of each RAID disk?

# Available RAID Acquisition Tools

- ▶ Vendors offering RAID acquisition or re-construction functions
  - ▶ Guidance Software EnCase (ex: [blog.1234n6.com](http://blog.1234n6.com))
  - ▶ X-Ways Forensics
  - ▶ AccessData FTK
  - ▶ Runtime Software
  - ▶ R-Tools Technologies
- ▶ Occasionally, a RAID system is too large for a static acquisition
  - ▶ Retrieve only the data relevant to the investigation with the sparse or logical acquisition method

# Exploration

- Software RAID today...
