

# Current Digital Forensics Tools

Software & Hardware

# Objectives

- ▶ Explain how to evaluate needs for digital forensics tools
- ▶ Describe available digital forensics software tools
- ▶ List some considerations for digital forensics hardware tools
- ▶ Describe methods for validating and testing forensics tools

# Evaluating Your Needs

# What Tools Work for You?

- ▶ Open-source tools will often provide the most features for the lowest price (free)
- ▶ Proprietary tools may have better support & wider recognition in the courtroom
- ▶ Questions to ask:
  - ▶ What OS's do you need to support for analysis? What OS will your tools run on?
  - ▶ Can the tool analyze more than one file system? Do you need to analyze more than one file system?
  - ▶ Is scripting of some type supported by your tool?
  - ▶ Does the vendor provide support consistently?

# Task Categories from CFTT / ISO 27037

- ▶ NIST has established the **Computer Forensics Tool Testing** ([CFTT](#)) program
  - ▶ We'll explore a subset of those categories
- ▶ Acquisition
- ▶ Validation & Verification
- ▶ Extraction
- ▶ Reconstruction
- ▶ Reporting

# Acquisition

- ▶ Making a copy of an original medium (drives or other media)
- ▶ Most important factor in acquisition is using the **proper** tool for the task **correctly**
- ▶ There are both hardware and software components to acquisition if a forensic bridge is used
- ▶ There are pros and cons to various acquisition formats
  - ▶ Ex: size vs ease of access / unallocated capture vs speed

# Validation & Verification

- ▶ **Validation:** confirming a tool works as intended
- ▶ **Verification:** proving that two sets of data are identical or that an output matches what's expected
  - ▶ Example: hash verification between image and source
  - ▶ Examples: filtering
    - ▶ Ignoring what's known (KFF / [NSRL](#))
    - ▶ File type verification by header
- ▶ Both can be tested using existing images
  - ▶ Ex: CFReDS: <https://www.cfreds.nist.gov/>

# Extraction

- ▶ **Extraction:** the part of the investigation where data is recovered from evidence
- ▶ Subfunctions of extraction:
  - ▶ Data viewing
  - ▶ Keyword searching
  - ▶ Decompressing or uncompressing
  - ▶ Carving
  - ▶ Decrypting
  - ▶ Bookmarking or tagging

# Extraction (Cont.)

- ▶ Carving and decompression are typically automated
  - ▶ Determining what should be carved or decompressed is usually configurable by file type
- ▶ Decryption is supported by tools but will require recovery keys or different types of password attacks
  - ▶ **Dictionary attack:** using words related to the suspect to create a list of passwords for attempted access to files, volumes, etc
  - ▶ **Brute-force attack:** generating a sequence of passwords until determining the right password
    - ▶ Works 100% of the time, provided infinite time

# Reconstruction

- ▶ **Reconstruction:** recreating a suspect drive to demonstrate what happened during an incident
- ▶ Most suites have this built-in, but it can always be done manually provided an image
  - ▶ FTK Imager only captures images
  - ▶ FTK can write out images
- ▶ Many methods listed in the text - the idea is copying your acquired image/clone to another image/clone for additional testing or verification

# Reporting

- ▶ **Reporting:** collection of relevant information from your investigation
  - ▶ Tool report: generated automatically (generally from bookmarks)
  - ▶ Full report: prepared by an investigator but often references a tool report
- ▶ **Subfunctions:**
  - ▶ Bookmarking or tagging
  - ▶ Log reports
  - ▶ Timelines
  - ▶ Report generator

# Comparing Available Suites

- ▶ Text has a table comparing features between 4 common tool suites on page 282 (Table 6-1)
- ▶ Consider making something similar when determining your needs in forensic tooling
- ▶ Flexibility, reliability, and future support/expandability are all factors
  - ▶ Every shop will have different needs
- ▶ Consider keeping all tools for an extended period if allowed by license terms

# References

- ▶ *Guide to Computer Forensics and Investigations*
  - ▶ ISBN: 9780357688595

# Software Tools

# Command Line Tools

- ▶ Historically - system administration tools were manually used for forensics
- ▶ Norton DiskEdit is a command line tool
- ▶ Command line tools are lightweight to run, but can have a higher learning curve than GUI tools
- ▶ The text calls out the `dir` command with the `/q` flag to get file owner as an example of a quick look that's built-in to Windows

# Linux Tool Examples

- ▶ SMART from ASR Data (only for LE/Military)
- ▶ Helix 3 from e-fense (\$239/yr membership)
- ▶ Kali Linux (free includes Autopsy and Sleuth Kit)
- ▶ Autopsy & Sleuth Kit (free)
  - ▶ Kali includes the original web version of Autopsy for operating The Sleuth Kit
  - ▶ There is a new Java based Autopsy available that runs on Windows & Linux
- ▶ Countless other open-source projects
  - ▶ This list has been updated recently: <https://github.com/cugu/awesome-forensics>

# GUI Tools

- ▶ **Graphical User Interface (GUI)** forensics tools can simplify digital forensics investigations
  - ▶ Additionally, simplify training for beginning examiners
- ▶ Most (not all) GUI tools are provided as suites
  - ▶ We'll use FTK in this course - CSC 419 explores Axiom from Magnet Forensics

# GUI Tools (Cont.)

- ▶ Advantages
  - ▶ Ease of use
  - ▶ Multitasking
- ▶ Disadvantages
  - ▶ Excessive resource requirements
  - ▶ Produce inconsistent results
  - ▶ Create tool dependencies

# Autopsy / The Sleuth Kit via Kali

# Exploring NSRL / KFF

# Index Search In FTK

# Reconstruction with FTK

# Reporting with FTK

# Hardware Tools

# Workstation Types

- ▶ **Stationary Workstation:** desktop machine with several bays and connectivity for external devices / peripherals
- ▶ **Portable Workstation:** mobile machine (typically a large laptop) with a similar amount of connectivity as a stationary workstation
- ▶ **Lightweight Workstation:** A more basic laptop with fewer connectivity options
- ▶ If you have the budget (and need) for it, it's likely more practical to have multiple systems that support diverse cases
  - ▶ Private orgs likely can streamline to what they deploy to their users

# Building vs. Buying

- ▶ Most of you already noted this in your previous labs, but there are pros and cons to building your own forensic workstations
- ▶ Pros
  - ▶ Save money
  - ▶ Customized to your exact needs
- ▶ Cons
  - ▶ No actual support

# Critical Components

- ▶ **Write Blocker / Forensic Bridge:** prevents writes to a disk
  - ▶ Can also use live CD/DVDs that support software write blocking (if allowed)
- ▶ Large amounts of storage, processing power, and memory
  - ▶ Unless you're only doing very targeted investigations

# Overall - YMMV

- ▶ Your mileage may vary...
- ▶ Every shop is going to have different needs

# References

- ▶ *Guide to Computer Forensics and Investigations*
  - ▶ ISBN: 9780357688595

# Validation & Testing

# Why?

- ▶ It is important to make sure the evidence you recover and analyze can be admitted in court
- ▶ You must test and validate your software to prevent damaging the evidence

# Using NIST Tools for Testing/Validation

- ▶ NIST publishes articles, provides tools, and creates procedures for testing/validating forensics software
- ▶ Computer Forensics Tool Testing ([CFTT](#)) project
  - ▶ Manages research on forensics tools
- ▶ NIST has created criteria for testing forensics tools based on:
  - ▶ Standard testing methods
  - ▶ ISO 17025 criteria for testing items that have no current standards

# Criteria for Testing

- ▶ ISO 5725 - specifies results must be repeatable and reproducible
- ▶ **Establish Categories for Tools:** group software according to categories of artifacts they retrieve or similar
- ▶ **Identify Category Requirements:** describe the technical features a tool must have to be in that category
- ▶ **Develop Test Assertions:** Find/create cases that can be verified in existing tools and use them to test new tools
- ▶ **Document a Test Method:** document how to test the tool
- ▶ **Report Test Results:** describe the results in a format that complies with ISO 5725

# Validate All Tools You Use

- ▶ Always verify your results by performing the same tasks with other similar forensics tools
- ▶ You don't have redo every case in an additional tool
  - ▶ You should verify each artifact types in different tools
  - ▶ Spot checking is good too (quality assurance measures in certain accreditations can drive this)

# Examination Protocol

1. Perform the investigation with one tool
2. Verify your results with a disk editor (or another qualified tool)
3. Compare outputs of both tools

# Upgrade Protocol

- ▶ Test at any
  - ▶ New tool releases
  - ▶ OS patches and upgrades
- ▶ If you find a problem, report it to forensics tool vendor
  - ▶ Do not use the forensics tool until the problem has been fixed
- ▶ Use a test disk for validation purposes
- ▶ Check the Web for new editions, updates, patches, and validation tests for your tools
